Sickle cell disease, an inherited blood disorder, is a public health problem for many tribal and rural caste communities in India. Many community members with the condition feel doubly disadvantaged – by nature and by the State. Why is this disease more prevalent among such communities? Is the disease inherent to such tribal communities, or is this a myth? As Prasanna Kumar Patra reveals, ongoing sickle cell control programmes in India seem to be better at creating social and ethical issues than they are at controlling the disease.

**Double discrimination!**

In the exercise center, a woman sits and is visibly sweating. As she breathes heavily, she says, “I have sickle cell disease.”

Is the disease inherent to such tribal communities, or is this a myth? As Prasanna Kumar Patra reveals, ongoing sickle cell control programmes in India seem to be better at creating social and ethical issues than they are at controlling the disease.

Some tribe members in India are conducted long-term regular blood transfusion treatment. In the case of creating a ‘saviour sibling’, what is the real motive? And who will bear the financial burden of the new-born child? These are the questions that the parents have to answer, who are not being considered in the public health policy guidelines.

The disease burden is huge and it only impacts the sickle cell patients, their children and future generations. The disease also affects the families, who have to bear the financial burden of the child. The double disadvantage experienced by sickle cell patients is not only medically but also on the social and psychological aspects.

Creating a ‘saviour sibling’ in India

The development of genetic technology has broadened the range of inherited disorders that can be identified almost overnight. Alas, a genetically inherited blood disorder, is prevalent in the south of China. The situation of families with thalassaemia-affected children highlights the need for a number of ethical and social issues related to the healthcare system in China, including the one child policy, and reproductive decision-making. And, as Sull’s research reveals, it is these issues which make the study of thalassaemia significant in China.

One question that many tribal people ask is why is it mainly among tribal communities, or is this a myth? As Prasanna Kumar Patra reveals, ongoing sickle cell control programmes in India seem to be better at creating social and ethical issues than they are at controlling the disease.
